ABSTRACT
Trust is essential for all online transactions adoption and usage including online banking. In this paper, online banking trust was addressed through empirical evidence from the survey conducted in Jordanian commercial banks. An extended Technology Acceptance Model (TAM) framework used in this study. Partial Least Squares (PLS) to analyze the data, which was composed of 198 questionnaires conducted with bank’s customers in Jordan. The results confirm that trust increases if users perceive online banking to be useful whereas perceived ease of use fails to predict Jordanians’ intention to accept and use online banking. The findings from this study are useful for policy makers, banking sectors and financial practitioners to enhance the use of online banking services among Jordanians.

Key words: Online Banking, TAM, Ease of Use, Usefulness, Trust.

INTRODUCTION
Within the recently growing advances in Information Technology innovations, many aspects of human life as well as performance of organizations have been revolutionized. This is especially more realized through the significant evolution of the Internet that has changed life for the last decade of the 20th century. Such rapid changes resulted by this promising technology have influenced the banking sectors [1].

Due to the increasing importance of such rapid technological changes, Information and Communication Technology (ICT) has been increasingly realized as a major driver in business development of banking sectors. Therefore, it is necessary for incorporation of Information Technology innovations in various departments of banking sectors to offer advanced and varied services, accelerate their performance, reduce in expenditure, and achieve more effective productivity [1-4]. In relation to the benefits of online banking for banking sectors, online banking is capable of offering provide competitive advantages, providing cost efficiencies, reaching customers at different and distanced geographical areas, setting up a brand name, and offering customized services. Concerning customers, either individuals or companies, online banking has features that enable customers not only to carry out or conduct banking transactions such as transfer of funds applications of loans, opening of fixed deposit account and letter of credit or investment activities but also enable them to manage their personal finance through facilities such as importing data into
personal accounting software and account aggregation. Using online banking, customers can financial transactions anytime and anywhere [5, 6]. Although online banking is useful and advantageous for both banks and customers, there are still several underlying issues that should be addressed and taken into account by interested bank sectors. One of the most crucial issue is trust [3, 6]. For instance, some previous studies showed that trust is one of the major issues for customers to accept the applications of online banking [7, 8]. Other studies indicated that customers are not used to applying such online transactions, especially online banking. This is primarily due to the issue of trust as well as risk concerns among users or customers. It was also found that there is reluctance among customers in relation to provision of sensitive information to banks’ websites and applications. This is because they worry about misusing debit and credit cards, which underlies their lack of trust [6, 9]. As pointed out by [9] and [10], one of the most important indicators of the success to many information system innovations is gaining customers’ trust. Trust is also one of the essential aspects of online banking since it results into customers’ acceptance of such services. In addition, trust is regarded as the major element in establishing a long-term relationship between banking sectors and customers. However, customer lack of trust is still a major barrier to in acceleration of the adoption of online transactions especially, acceptance and usage of online banking [1, 7, 11, 12].

The present study aimed at shedding some light on the influence of Jordanian customers’ Perceived Ease of Use (PEOU) and Perceived Usefulness (PU) of online banking on their trust, acceptance and usage of such services. The study also investigated trust as an important element in the success and growth of online banking and determined the key trust factors as well as their effects on Jordanian users’ intention and decision to accept and use online banking in performing financial and non-financial transactions. The results of the present study are expected to assist practitioners and researchers in Information System (IS) to manage and strategize elements in establishing trust, which will, in turns, foster or strengthens customers’ acceptance of online banking and financial services. Such findings will also help banking sectors to offer more customer-oriented services and develop e-commerce competitive advantage.

**MAIN RESULTS**

The results of the parameter estimates and statistical for all the four constructs: ITU, PEOU, PT and PU show that they are all valid measures of their respective constructs. The overall results of the measurement model satisfactorily support the model in terms of reliability, convergent and discriminant validity. The study used the Partial Least Square (PLS) technique and Path Coefficient (ß) criterions with the aim of testing the six research hypotheses. The results of the measurement model analysis shown in Figure 1. The study investigated the impact of PEOU on behavioural intention to adopt online banking (H1) and the relationships between PEOU and PU (H2) and PT (H3). The results of path coefficient (ß) and R² values demonstrate that PEOU has no significant effect on users’ or customers’ behavioural intention to use online banking as the path coefficient was only 1.8%. Furthermore, the estimation of path coefficient and R² between PEOU and intention to use online banking is equal to zero. Such result indicates that there is no significant effect between these two constructs. However, it was interesting that the results support the significant relationship between PEOU and PU to use online banking. This is evidenced by the estimated path coefficient between PEOU and PU (63.2%). There is also a significant effect of PU on PT (H4) and behavioural intention to use online banking (H5) as indicated by the results of the path coefficient (ß) and R². The relation between PT and ITU (H6) is a significant where estimated path coefficient had reached 46.4%.
CONCLUSION

The results of the present study support the conventional views of the effect of PEOU and PU as independent variables on the PT in Online banking. The study also provided insights into the role of PEOU, PU, and PT in predicting the intention to use Online Banking among Jordanian consumer customers of commercial banks in the city of Irbid, which is the second largest city in Jordan. The study adopted the PLS technique in testing the proposed research hypotheses. A general descriptive analysis was conducted, to obtain a summary about the respondents’ demographic characteristics by using the response means, frequencies, and standard deviations. Then, the data were analyzed by using the Partial Least Squares (PLS) method, with SmartPLS 3 software, which involved measurement and structural model to testing the proposed research hypotheses.
